HOMELAB · OCTOBER 2026

Homelab Command Center

A dashboard for a Proxmox and Unraid homelab. It shows host and disk activity as it happens, checks every service, answers questions with a local AI model, and runs updates safely.

React 18 · Python backend · Proxmox VE · Unraid · Intel Arc A310 · llama.cpp

29
services monitored

rolling disk history

01 · OVERVIEW

What needs attention, and the buttons you use most

A status line at the top says “All clear” or lists what needs attention, and each item opens its page. Below it: power for the gaming PC, a DNS pause, an update check, and a one-line box for asking the local Qwen model.

One tap from the phone

Wake or sleep the gaming PC, pause ad blocking, or check for updates without leaving the first screen.

Safe buttons

Every action confirms first with a button named after what it does, and only works from the dashboard itself.

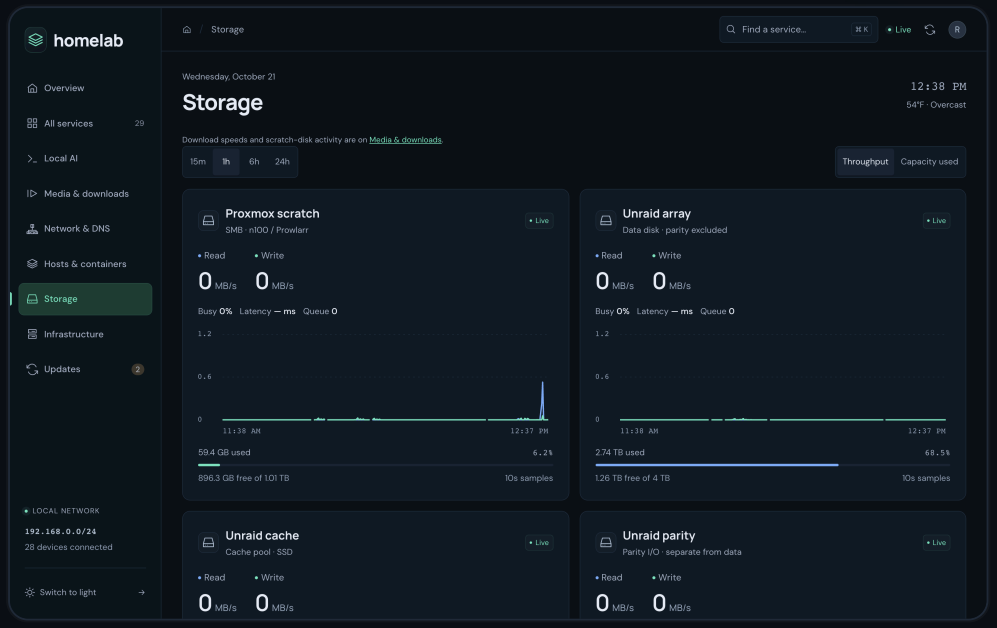

Missing data stays missing

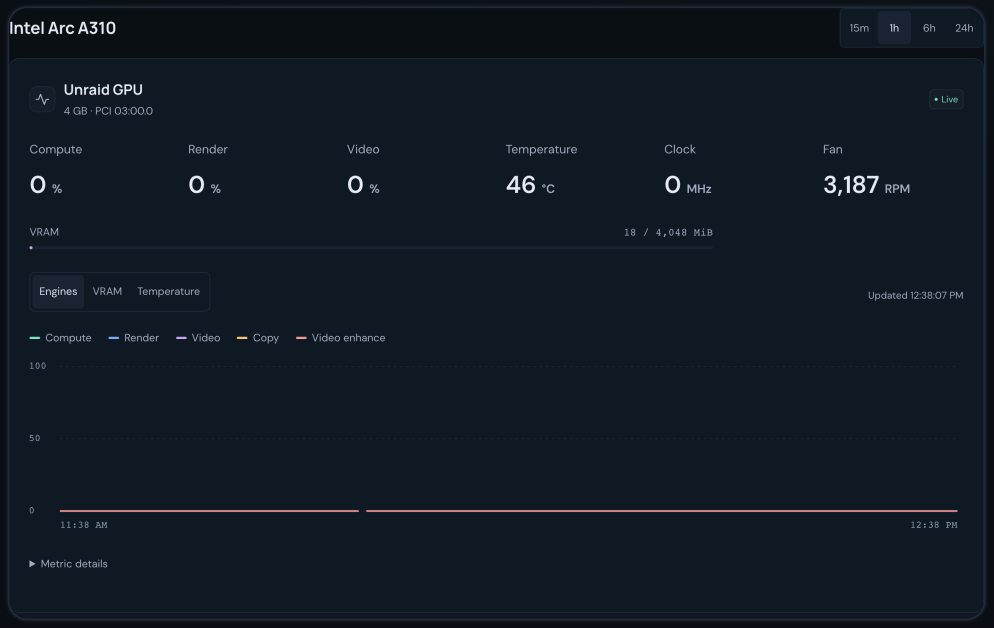

Each reading has a timestamp. If a source stops answering, the tile shows “—” instead of zero.

02 · STORAGE & GPU

Disk activity and the Arc A310 GPU

Read and write speed, busy time and latency for each disk, taken from the Linux kernel’s counters. The Arc A310 panel, now on the Local AI page, shows render, compute and VRAM use.

Cache forecast

Estimates when the Unraid cache will fill and starts the mover before it does.

Shares remount themselves

A timer checks network shares every two minutes and remounts any that stop responding.

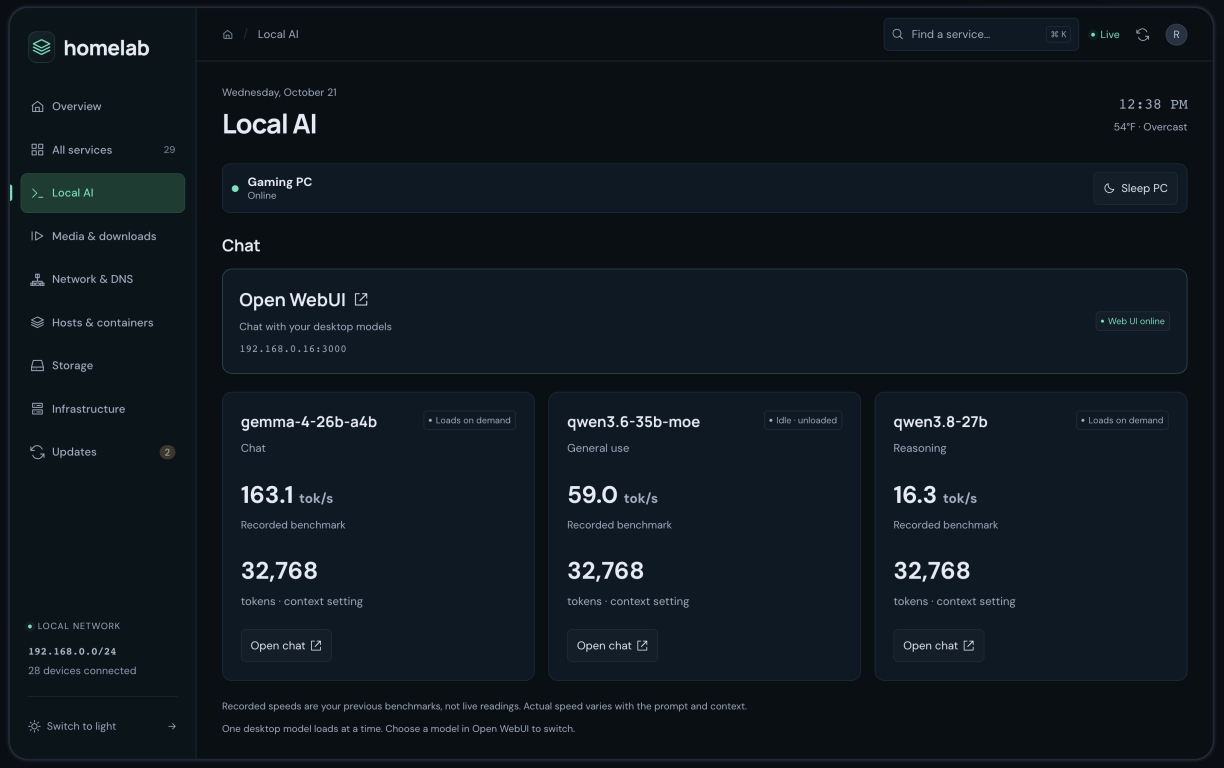

Gaps in the chart

After a reboot the chart shows a gap. It doesn’t fill in made-up numbers.

03 · LOCAL AI

AI models that run at home

Three models run on an RTX 5070 Ti through llama.cpp, and the page shows whether the gaming PC is on, with Wake and Sleep buttons. A small Qwen model on the Arc A310 answers questions about the homelab and shows the data it used.

Measured speeds

Gemma 4 26B 163 tok/s

Qwen 3.6 35B MoE 59 tok/s · 32K

Qwen 3.8 27B 16 tok/s

Shows its sources

Each answer lists the readings it was given, when they were taken, and what was left out.

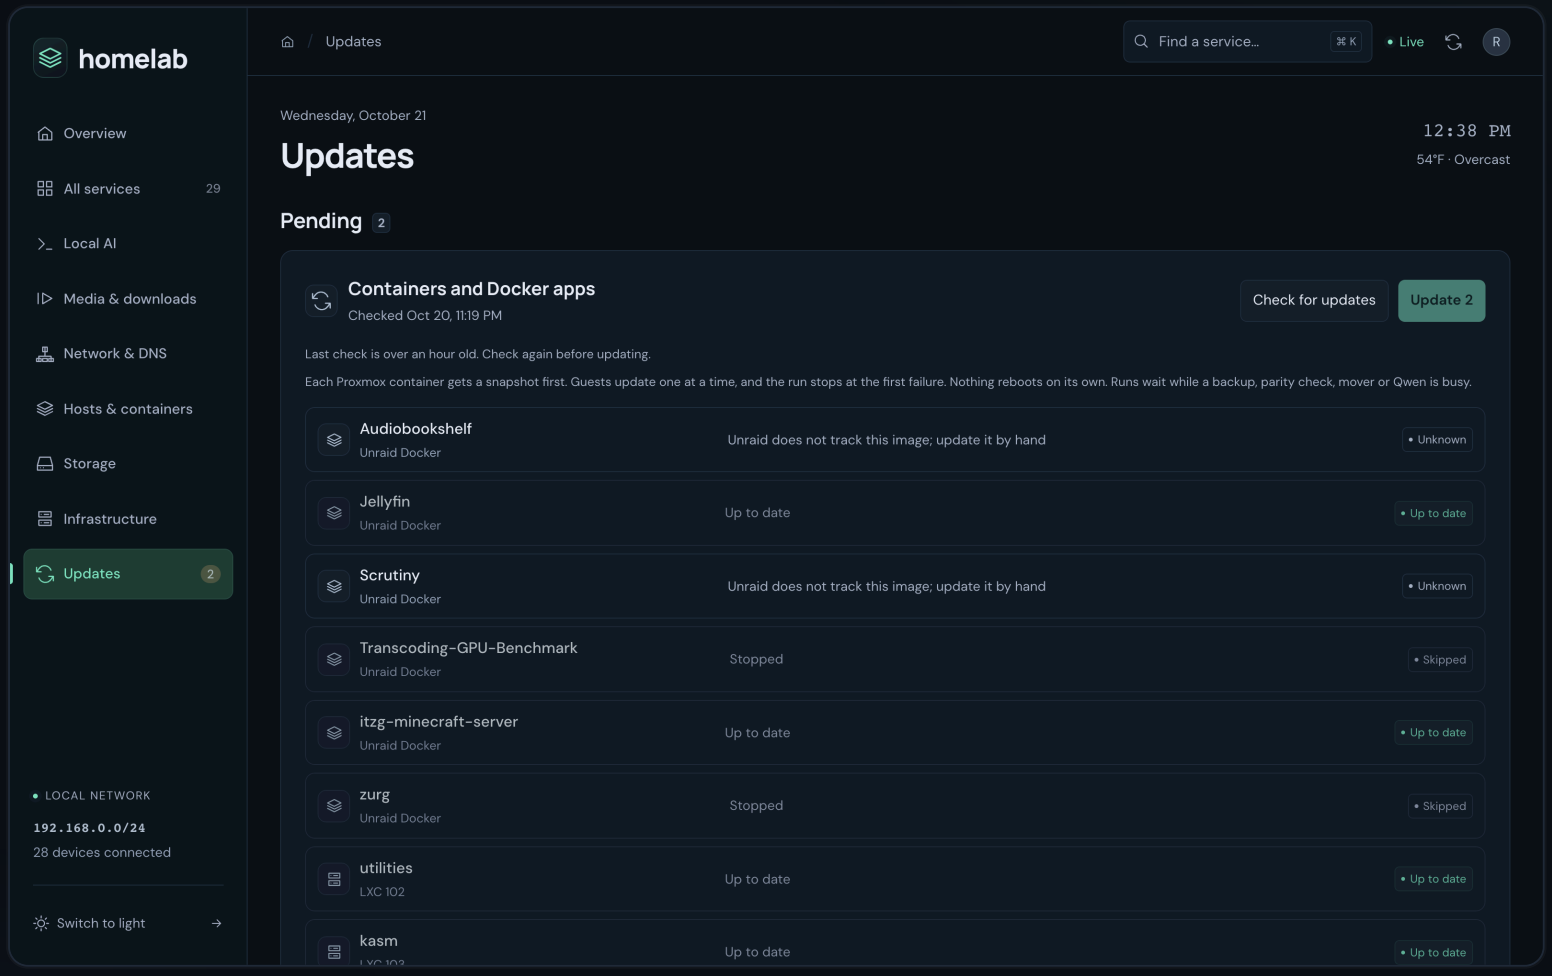

Read-only tools

Models in Open WebUI can check the servers through a fixed set of SSH commands. They can’t run anything else.

04 · UPDATES

Updates run one guest at a time

Each Proxmox container gets a snapshot before `apt upgrade`. Docker apps update through Unraid's own updater. The run stops at the first failure and shows the rollback command.

05 · FLEET

Every VM, container and Docker app in one list

Host health for Proxmox and Unraid at the top, then CPU, memory and state for every guest. Machines that are off on purpose show in grey and sort to the bottom.
